Research Question

Do situations of
violently helping others
(emergency assistance)
in video games
reinforce

- **violent behavior,**
 - **helping behavior,**
 - **or both**
- ?

Why it's important

- Most popular genre are shooters (58%), directly followed by role-playing-games (55%) (Annenberg Studies on Computer Games Group)
- Situations of emergency assistance are typical for role-playing-games, where the heroic player has to protect “good” people by fighting “evil” people (e. g. saving a princess from a villain).
- And situations like these are also relevant in real-life, as they resemble extreme forms of situations of moral courage (e. g. the case of „Dominik Brunner“).

Current State of Research

- The General Aggression Model (GAM) predicts that in-game violence reinforces real-life aggressive behavior and reduces real-life prosocial behavior.
- Recent meta-analyses (Anderson & Bushman, 2001; Anderson 2004; Anderson et al., 2010) support this prediction.
- The General Learning Model (GLM) predicts that in-game helping reinforces real-life prosocial behavior.
- Early studies by Greitemeyer and Osswald (2009; 2010) and Gentile et al. (2009) support this prediction.

- 14. Literature

Violent Behavior (H_3)

- In comparison to a pure violent situation, situations of emergency assistance also contain some form of helping.
- But in situations of emergency assistance, helping occurs as nonviolently as possible.
- Therefore, in pure violent situations more violent behavior should occur than in situations of emergency assistance.

Helping Behavior

Replication

H₄: In-game helping behavior increases real-life helping behavior.

New

H₅: In-game emergency assistance increases real-life helping behavior.

New

H₆: In-game helping behavior increases real-life helping behavior more than in-game emergency assistance.

- 10. General Discussion
- 13. Extras
- 14. Literature

Helping Behavior (H_6)

- In comparison to a pure helping situation, situations of emergency assistance also contain some form of violence.
- But there is a strong inhibition to use violence against others.
- If helping is only possible by using violence, chances are that helping does not occur at all.
- Therefore, in pure helping situations more helping behavior should occur than in situations of emergency assistance.

Independent Variables

IV A: In-game killing

- **Killing:** In-game characters (bandits) have to be killed in order to solve a quest. This is accomplished by fighting.
- **No Killing:** In-game characters cannot be killed. The quest is accomplished by sneaking.

IV B: In-game helping

- **Helping:** The questgiver (a damsel in distress) has to be helped in order to solve the quest.
- **No Helping:** The questgiver (a damsel without distress) cannot be helped.

Dependent Variable A: **Violent Behavior**

- Competitive Reaction Time Task (CRTT)
- Cover story: compete 25 rounds against another participant in a reaction time test
- At the beginning of each round, set the intensity and duration of a sound shock your opponent will receive if he loses
- There is no opponent, participant wins 12 rounds
- Violent behavior is operationalized as the product of intensity and duration in the **first** round
- Training phase prior to video game in order to minimize time between treatment and measurement

5. Dependent Variables
6. Subjects
7. Manipulation Checks
8. Results
9. Discussion
10. General Discussion

Dependent Variable B: **Helping Behavior**

- Willingness to assist (computer based)
- Cover story: graduand wants to investigate how much concentration remains after long experiments
- Participant has to indicate how many items (between 0 and 200) he/she wants to solve; program crashes afterwards
- Long duration of experiment to minimize time pressure

Violent Behavior

- The hypothesis „In-game violence increases **violent behavior**“ was confirmed.
- The hypothesis „In-game emergency assistance increases **violent behavior**“ was marginally confirmed.
- But one third of the participants suspected that the CRTT measures aggression **before it was conducted**. This could have reduced the effect size due to social desirability.
- All in all, emergency assistance seemingly increases **violent behavior**.

8. Results
- ➡ 9. Discussion
10. General Discussion

13. Extras
14. Literature

Helping Behavior

- The hypothesis “In-game helping increases helping behavior” could not be confirmed. This could be due to the weak treatment.
- The hypothesis “In-game emergency assistance increases helping behavior” could not be confirmed. Seemingly, the opposite seems to be true.

10. General Discussion

- 1. Overview
- 2. Hypotheses

Usefulness for advancement of theories

- Results replicate preceding studies
 - In-game violence increases violent behavior
 - In-game helping could increase helping behavior
- First insights about emergency assistance
 - In-game emergency assistance seemingly increases violent behavior and at the same time reduces helping behavior
 - Results in accordance with moral management model
 - In the light of this model, one could say that in-game **emergency assistance does not lead to selflessness, but to self-righteousness**
 - But replication is needed as these hypotheses were not postulated a priori

10. General Discussion

- 14. Literature

Usefulness for applications and everyday life

- In video games, assisting a character in an emergency seems to undermine moral thinking (at least for a short amount of time)
- There is a risk that regular use of violent games could permanently reduce moral thinking
- Do we have to shun from violent entertainment or can we protect ourselves from the negative consequences?
 - Maybe we should constantly remind ourselves that our actions are not in accordance with moral rules?
 - Maybe we should not disengage the moral concerns but instead suffer from the arising negative emotions even if this reduces the entertaining effect?

Thank you very much for your interest !
